Independent numerical validation of noisy-reservoir memory
A Full physical trajectories at fixed n = 32
k=3, r=1
k=5, r=3
k=7, r=5
Measured one-qubit Z
Hold cycles since write (symlog)
B One million independent trials per point
Exact reference
Sampling + 99% intervals
0 failures; upper bound
Logical error probability per hold cycle
Fresh input qubits k = r + 2
C Exact model values; q = 0.9
Active repair: one-qubit readout
Passive copies: optimal full-state readout
Cycles above distinguishability 0.45
k = r + 2 for active reservoir
D Size can help below a uniform ceiling
Pulse threshold from q^(L+1) > 0.1
Last pulse delay with trace distance > 0.1
Total qubits n; fixed k = 1
